# *Dynamic Programming*

- Divide and conquer
- Example applications
  - Knapsack problem
  - Partition problem
  - Sequence alignment using local similarity
    - Matching one sequence onto another
    - Matching parts of one sequence onto parts of another

# *Divide and Conquer*

- Formulate the solution to a large problem in terms of solutions to smaller problems
  - Binary search
  - Dynamic programming

# *Dynamic Programming Components*

- Solution must be formulated as a recurrence relationship or recursive algorithm
- There must be an evaluation order that solves smaller problems before larger ones
- Storing the solutions to smaller problems makes solving the larger problem computable via table lookup
  - There cannot be too many “smaller” problems

# *Fibonacci Number by Recursion*

- $F(n) = F(n - 1) + F(n - 2)$ 
  - where  $F(0) = 0$ ,  $F(1) = 1$
  - 0, 1, 1, 2, 3, 5, 8, 13, ...
- Compute using recursion

```
def F(n):  
    if n < 2:  
        return n  
    else:  
        return F(n - 1) + F(n - 2)
```

# *Recursion Complexity\**

- Let  $f(n)$  be “the number of steps to compute the  $n$ th Fibonacci number using this algorithm”. We'll compute both upper bounds and lower bounds on  $f(n)$ .
- We know that for  $n > 1$  and constant  $c$ ,  
$$f(n) = f(n-1) + f(n-2) + c$$

# *Complexity Upper Bound*

- Since  $f(n-1) > f(n-2)$  and  $c$  is expected to be small, we can say that  $f(n) \leq 2 * f(n-1)$ .  
That means that:
  - $f(n) \leq 2 * 2 * f(n-2)$ , or
  - $f(n) \leq 2 * 2 * 2 * f(n-3)$ , or more generally,
  - $f(n) \leq 2^k * f(n-k)$ .
  - For  $k = (n-1)$ ,  $f(n) \leq 2^{n-1} * f(1)$ .
- Since  $f(1)$  is a constant,  $F(n)$  is  $O(2^n)$ .

# *Complexity Lower Bound*

- Since  $f(n-2) < f(n-1)$ , and  $c$  is expected to be small, we can say that  $f(n) \geq 2 * f(n-2)$ . Using a similar analysis to the one above, we get that  $F(n)$  is in  $\Omega(2^{n/2})$ .
- Both lower bound and upper bound are exponential. We can therefore say that  $F(n)$  is an exponential algorithm.

## *Alternate Analysis*

- $F(n) = (\Phi^n - (-\Phi)^{-n}) / \sqrt{5}$ 
  - The Golden Ratio  $\Phi$  is approximately 1.618
- Because the leaves of our recursion are  $F(1) = 1$ , there must be at least  $F(n)$  leaves in order to sum up to  $F(n)$ , which means the entire recursion runs in exponential time

# *Fibonacci Number by Dynamic Programming*

- We have a recurrence relationship
  - $F(n) = F(n - 1) + F(n - 2)$
- We have an evaluation order which solves smaller problems before larger ones
  - $F(1), F(2), \dots, F(n-2), F(n-1), F(n)$
- There are not too many smaller problems
  - Exactly  $(n - 1)$
- Dynamic programming is applicable

# *Fibonacci Number by Dynamic Programming*

- Compute using dynamic programming

```
def F(n):  
    f = [0, 1]  
    for k in range(2, n + 1):  
        f.append(f[k - 1] + f[k - 2])  
    return f[n]
```

- Complexity is  $O(n)$  from “for” loop
  - Improvement over exponential time comes from storing and looking up intermediate results

# *Sequence Alignment using Dynamic Programming*

- Similar to dynamic programming solutions to the approximate string matching problem
- Needleman, S.B. and Wunsch, C.D. A General Method Applicable to the Search for Similarities in Amino Acid Sequence of Two Proteins. *J. Mol. Biol.*, **48**, pp. 443-453, 1970.
- Smith, T.F. and Waterman, M.S. Identification of Common Molecular Subsequences. *J. Mol. Biol.*, **147**, pp. 195-197, 1981.

# *Approximate String Matching*

- Given two character strings A (length  $n$ ) and B (length  $m$ ), what is the minimum number of substitutions, insertions and deletions required to transform A into B?
- Alternatively, what fragments of A and B are matched?

# *Cost Metric*

- Best solution has the minimum total cost of:
  - substitution cost
    - replacing  $A_i$  with  $B_j$
  - insertion cost
    - inserting  $B_j$
  - deletion cost
    - skipping  $A_i$

# *String Matching using Dynamic Programming*

- Consider the last character from strings A and B. The possibilities are: (1) they match, (2)  $A_n$  is matched to something before  $B_m$ , (3)  $B_m$  is matched to something before  $A_n$ .

# *String Matching using Dynamic Programming*

- Recurrence relationship
  - Let  $\text{cost}(A_n, B_m)$  be the cost of matching two strings where  $A_n$  and  $B_m$  are the last characters:  
$$\text{cost}(A_n, B_m) = \text{minimum}(\begin{aligned} &\text{cost}(A_{n-1}, B_{m-1}) + \text{substitution}(A_n, B_m), \\ &\text{cost}(A_n, B_{m-1}) + \text{insertion}(B_m), \\ &\text{cost}(A_{n-1}, B_m) + \text{deletion}(A_n) \end{aligned})$$

# *String Matching using Dynamic Programming*

- Boundary conditions
  - Let  $A_1$  and  $B_1$  denote the first character of each string and insert dummy characters  $A_0$  and  $B_0$ ,  
 $\text{cost}(A_0, B_j) = \text{initial\_insertion}(B_0 \text{ through } B_j)$   
 $\text{cost}(A_j, B_0) = \text{initial\_deletion}(A_0 \text{ through } A_j)$   
 $\text{cost}(A_0, B_0) = 0$
  - Note that initial insertion and deletion costs may be different than internal ones

# *String Matching using Dynamic Programming*

- Order of evaluation
  - To compute  $\text{cost}(A_n, B_m)$ , we need the results from  $\text{cost}(A_{n-1}, B_{m-1})$ ,  $\text{cost}(A_n, B_{m-1})$ , and  $\text{cost}(A_{n-1}, B_m)$
  - By induction, we need to compute  $\text{cost}(A_i, B_j)$  for all  $i < n$  and  $j < m$
- The number of intermediate solutions is  $n \times m$

# *String Matching using Dynamic Programming*

- Computing the cost
  - The  $n \times m$  nature of the intermediate solutions suggests that they may be stored in a two-dimensional array, “H”
  - The evaluation order requires that the array be filled in a left-to-right, top-to-bottom fashion
  - The cost of aligning the two strings is in the cell at the bottom right corner

# *String Matching using Dynamic Programming*

- Example
  - Substitution cost = 0 if  $A_i = B_j$ ; 1 otherwise
  - Insertion and deletion costs = 1
  - Match “abbc**d**” to “acc**d**”

| H |   | a | b | b | c | d |
|---|---|---|---|---|---|---|
|   | 0 | 1 | 2 | 3 | 4 | 5 |
| a | 1 | 0 | 1 | 2 | 3 | 4 |
| c | 2 | 1 | 1 | 2 | 2 | 3 |
| c | 3 | 2 | 2 | 2 | 2 | 3 |
| d | 4 | 3 | 3 | 3 | 3 | 2 |

The best score is 2

# String Matching using Dynamic Programming

- Recovering the alignment
  - Trace back from  $H_{n,m}$
  - Find which operation resulted in the value of the cell and proceed to corresponding cell:
    - match  $\rightarrow$  above-left
    - insert  $\rightarrow$  above
    - delete  $\rightarrow$  left

| H |   | a | b | b | c | d |
|---|---|---|---|---|---|---|
|   | 0 | 1 | 2 | 3 | 4 | 5 |
| a | 1 | 0 | 1 | 2 | 3 | 4 |
| c | 2 | 1 | 1 | 2 | 2 | 3 |
| c | 3 | 2 | 2 | 2 | 2 | 3 |
| d | 4 | 3 | 3 | 3 | 3 | 2 |

a-c**cd**

a**c**-**cd**

a**bb**cd

a**bb**cd

# *String Matching using Dynamic Programming*

- Recovering the alignment
  - The operation that resulted in a particular cell value may either be recorded when computing H, or recomputed during trace back
  - There are multiple back traces when a cell on the optimal path may be reached via more than one operation
  - All these back traces share the same best score and there are no back traces with a better score

# *Sequence Alignment*

- Given two sequences, where are the similar fragments ...
  - if the two sequences are mostly similar?
    - global alignment where all residues are matched
  - if only parts are similar?
    - local alignment where only some residues are matched

# *Sequence Alignment*

- This is similar to approximate string matching
- Algorithm transformation
  - substitution costs replaced by similarity scores
  - insertion and deletion costs replaced by gap penalties
  - best solution being maximum instead of minimum

# *Sequence Alignment*

- The recurrence relationship is typically written as

$$H_{i,j} = \text{maximum}(\begin{array}{l} H_{i-1,j-1} + S(A_i, B_j), \\ H_{i-1,j} - \text{gap penalty}, \\ H_{i,j-1} - \text{gap penalty} \end{array})$$

# *Amino Acid Score Matrices*

- Substitutions scores are typically stored in a matrix whose rows and columns are residue types and whose cells are the similarity between the two types of residues
  - Genetic code matrix
  - PAM 250 (Dayhoff)
  - BLOSUM

# *Amino Acid Score Matrices*

- Dynamic programming algorithm for sequence alignment is the same regardless of which matrix is used
- Matrix construction will be covered in another lecture

# *Needleman & Wunsch*

- Global alignment method for finding identical matching residues
- Used multiple genetic code score matrix for testing evolutionary distance hypotheses

# *Needleman & Wunsch*

- Genetic code score matrix
  - 1 for identical amino acids
  - 0 for amino acid pairs whose codons have no possible corresponding base
  - Range of values between 0 and 1 for pairs with maximum of one or two corresponding bases
- Constant gap penalty per insertion/deletion
  - Values range from 0 to 25

# *Needleman & Wunsch*

- Procedure for comparing A to B
  - Produce a set of sequences by randomizing B
  - Align randomized set against A to obtain “random” score average and standard deviation
  - Align B to A to find a “maximum match” score
  - Compute number of standard deviations “maximum match” score is from “random” score

# *Needleman & Wunsch*

- Why not examine just the best solution?
  - Dynamic programming will always produce the best answer for the problem at hand, whether the question is meaningful or not
  - The significance of the question can only be measured relative to some control
  - If “maximum match” score is more than 3 standard deviations above “random” score, the result is considered significant

# *Needleman & Wunsch*

- Results and conclusions
  - Alignments between  $\beta$ -hemoglobin and myoglobin were significant for all seven sets of parameters tested
  - Alignments between ribonuclease and lysozyme were not significant for any of the seven sets of parameters tested
  - Beware of global alignments when the two sequences are not “closely” related

# *Smith & Waterman*

- Local alignment method for identifying best matching fragment
- Score matrix remains unchanged
- Extends gap penalty to be length-dependent
  - Recurrence relationship changes

# *Smith & Waterman*

- Recurrence relationship with length-dependent gap penalty

$$H_{i,j} = \text{maximum}(\begin{aligned} &H_{i-1,j-1} + S(A_i, B_j), \\ &\text{maximum}(H_{i-k,j} - W_k, 1 \leq k < i), \\ &\text{maximum}(H_{i,j-m} - W_m, 1 \leq m < j), \\ &0 \end{aligned})$$

# *Smith & Waterman*

- $W_x$  is the penalty for a gap of length  $x$
- Score at any cell should not drop below zero, which would penalize subsequent fragment alignments

# *Smith & Waterman*

- Best aligned fragments are found by starting at cell with highest score and trace back to cell with zero score
- More aligned fragments may be found by back traces starting at other high scoring cells

# *Summary*

- Dynamic programming is a divide-and-conquer method for solving problems with recurrence relationships
  - Results from intermediate results are stored so they do not need to be recomputed (space-time trade-off)
  - There is always a “best” solution, but it still may not be a reasonable solution

# *Homework*

- Implement the Smith-Waterman algorithm
  - Write a function which accepts the following arguments:
    - 2 sequences
    - a similarity measure between sequence elements (either a function which takes two residue types as arguments, or a two-dimensional matrix)
    - a gap penalty function, which takes the gap length as an argument

# *Homework*

- Implement the Smith-Waterman algorithm
  - Your function should return the common subsequence with the highest score
  - For grading purposes, your function should also print out the score matrix
  - *E-mail both your code and program output to [conrad@cgl.ucsf.edu](mailto:conrad@cgl.ucsf.edu)*

# Homework

- Input data
  - Apply your code to the example from the Smith & Waterman paper
    - **CAGCCUCGCUUAG** vs. **AAUGCCAUGACGG**
    - $S(A_i, B_j) = 1$  if  $A_i = B_j$ ;  $-1/3$  otherwise
    - $W_k = 1.0 + (1/3) * k$
    - Also try **GCCUCGCUUAG** vs. **UGCCGCUGACGG**
  - Your alignment and score matrix should match those published in the paper
